HIV transmission in the UK within Black African communities: how common is it and how do we prevent it?

Dr Valerie Delpech
We gratefully acknowledge persons living with HIV, clinicians, health advisors, nurses, microbiologists, public health practitioners, data managers and other colleagues who contribute to the surveillance of HIV and STIs in the UK
Heterosexual men and women

An estimated 59,500 people living with HIV in 2013 in the UK had acquired their infection through heterosexual contact. There has been a decline in the number of new HIV diagnoses reported among heterosexual men and women in recent years (from 4,890 in 2004 to 2,490 in 2013) due to fewer diagnoses among people born in sub-Saharan Africa. This has also resulted in a decline in the number and proportion of people diagnosed late (from 3,100 (65%) in 2004 to 1,200 (58%) in 2013). However, the number of reports among people who probably acquired HIV in the UK remains high at around 1,500 per year.

The large majority of black-African people living in the UK do not have HIV. Nevertheless, in 2013, an estimated 38,700 black-Africans were HIV positive and this group constitutes two-thirds (65%, 38,700) of all heterosexual people living with HIV. The HIV prevalence rate among black-African heterosexuals is 56 per 1,000 population aged 15-59 years (41 per 1,000 in men and 71 per 1,000 in women). Almost two in five (38%) black-African men and one in three (31%) black-African women living with HIV remained unaware of their infection. Rates of undiagnosed infection were higher outside of London at 50% and 41%, respectively.

Estimates of UK-acquired HIV infection among persons born abroad

A new method to assign country of HIV infection among heterosexuals born abroad and diagnosed with HIV

Brian D. Rice\textsuperscript{a,b}, Jonathan Elford\textsuperscript{b}, Zheng Yin\textsuperscript{a} and Valerie C. Delpetch\textsuperscript{a}

Objective: To apply a new method to ascertain likely place of HIV infection among persons born abroad and diagnosed with HIV in the United Kingdom (UK).

Design: Analysis of heterosexual adults born abroad, diagnosed with HIV in the UK between 2004 and 2010, and reported to the national HIV diagnoses database.

Methods: Year of infection was ascertained by applying an estimated rate of CD4 cell count decline between an individual's CD4 cell count at diagnosis and estimates of CD4 count at infection. A person was classified as having probably acquired HIV while living in the UK if estimated year of infection was later than reported year of arrival in the UK.

Results: Of 10412 heterosexual adults born abroad included in the analysis, 85\% (9065) were of black-African ethnicity. We estimate that 33\% (25\%-39\%) of persons acquired HIV while living in the UK. This percentage increased from 24\% (16\%-39\%) in 2004 to 46\% (31\%-50\%) in 2010 (\(P<0.01\)). The estimate of 33\% is three times higher than national estimates of HIV acquired in the UK based on clinic reports (11\%) (\(P<0.01\)).

Conclusion: Assigning place of HIV infection using routinely available clinical and demographic data and estimated rates of CD4 cell count decline is feasible. We report a high and increasing proportion of persons born abroad who appear to have acquired their HIV infection while living in the UK. These findings highlight the need for continued targeted HIV prevention efforts, particularly among black-African communities.

New diagnoses among heterosexual men and women by probable place of acquisition, UK

- Acquired in UK, female
- Acquired abroad, female
- Acquired in UK, men
New HIV diagnoses\(^1\) among MSM by probable country of infection: UK, 2004-2013

\(^1\) Numbers have been adjusted for missing exposure category and region of birth.
New HIV diagnoses acquired by UK-born heterosexuals through sex outside the UK

Data from 2002-2010:

15% of UK born adults newly diagnosed with HIV reported acquiring infection abroad

Countries most commonly reported:

Thailand, South Africa, Nigeria, Spain, Zimbabwe and the USA

Compared to adults who acquired HIV in the UK, more likely to be:

- Heterosexual
- Older
- Contact with sex workers
How do we prevent HIV transmission

HIV is mostly transmitted from those unaware of their infection including those in acute infection.

whole system approach
wide range of effective biomedical and behaviour interventions
Tackling HIV transmission: Challenges and opportunities

- Role primary infection
- Improving testing uptake at GUM, GP and other settings
- Earlier diagnosis leads to improved survival and lower transmission
- Improving partner notifications
- Use of novel technologies (testing/prep)
- Role of faith leaders
- Condom uptake remains too low – serosorting is not safe
- Changing social networks with wide use of apps to find casual partners
- Increase in chemsex
- Role of TasP

Find a clinic

There are places where you can access a free, confidential HIV test all over the country.

You can choose a Sexual health clinic, where you'll get a full STI screening too, or a Community testing service, where you'll probably just be tested for HIV somewhere more local.

Testing for HIV is easier than ever and treatment means HIV positive people live as long as anyone else - so why not test?

Conclusions
Conclusions

- Evidence of ongoing HIV transmission among BME heterosexual communities in the UK with high rates of undiagnosed and late diagnoses.
- Expand and target testing with novel diagnostics could be scale up. HIV testing can be a gateway for more tailored approach, and access to, behavioral and biomedical interventions.
- Integrate HIV testing into routine care, eg GP, indicator diseases.
- Efforts to identify persons in primary infection. Once diagnosed, they should be offered earlier treatment and prioritise for partner notification.
- Other prevention strategies such as sex education and increased awareness or HIV, condom use must be sustained and strengthened.
- Mental health and non-harmful use of drugs and alcohol remain critical in the control of HIV and other STIs epidemic.
- These need to be individualised with greater engagement of peers and community groups in their delivery.
Implications for prevention II

HIV testing coverage in STI clinics continued to improve in 2013; 83% (180/216) of STI clinics achieved a coverage of 80% or more among MSM attendees, in line with British Association for Sexual Health and HIV (BASHH) guidelines [1] (including 43 clinics with a coverage rate above 90%). HIV test coverage among heterosexual attendees was lower: overall 67% coverage in England with only 35 clinics achieving coverage of 80% or more. To further improve HIV testing rates and achieve optimal coverage, clinics could:

a) Review local policies and training protocols;

b) Consider innovative approaches, which may include active recall and fast-track pathways to increase the frequency of HIV testing of MSM clinic attendees;

c) Work with local authority commissioners to decide upon the need to implement innovative testing services such as HIV self-sampling.

Local authority commissioners and service providers together could consider investing in innovative HIV testing activities delivered through clinical, community and outreach services. This could include the intensification of partner notification following the diagnosis of HIV infection. This is a highly effective way to detect undiagnosed HIV infections: in 2013, 7.3% of MSM sexual partners and 3.3% of heterosexual male partners of people diagnosed with HIV were also positive for HIV infection. STI clinics could review the performance of this service to see how improvements can be achieved.
Implications for prevention III

Important new evidence for the role of pre-exposure prophylaxis (PrEP) in the prevention of HIV has emerged in 2014, leading to the decision to offer PrEP to the control group in the UK PROUD trial for MSM at risk of HIV infection. Research on the cost-effectiveness and affordability of PrEP for people most-at-risk needs to be accelerated to allow relevant policy decisions to be taken at the earliest opportunity.

National and international treatment guidelines recommend early treatment to prevent onward transmission. People living with HIV and their health care providers can discuss starting ART to reduce their risk of transmitting HIV to their sexual partners. In 2013, 3,710 people who started ART had a CD4 count above 500 cells/mm$^3$ compared to 3,330 in 2012. Reassuringly, adherence levels among those initiating ART early are high, improving and in 2013, in line with adherence among those initiating ART at <350 cells/mm$^3$. 
PHE’s messages
Early diagnosis of HIV enables better treatment outcomes and reduces the risk of onward transmission. Have an HIV test if you think you may have been at risk. Get tested regularly for HIV if you are one of those most-at-risk:

**Men who have sex with men** are advised to have an HIV and STI screen at least annually, and every three months if having unprotected sex with new or casual partners.

**Black-African men and women** are advised to have an HIV test and a regular HIV and STI screen if having unprotected sex with new or casual partners.

Always use a condom correctly and consistently, and until all partners have had a sexual health screen.

Reduce the number of sexual partners and avoid overlapping sexual relationships. Unprotected sex with partners believed to be of the same HIV status (serosorting) is unsafe. For the HIV positive, there is a high risk of acquiring other STIs and hepatitis. For the HIV negative, there is a high risk of HIV transmission (over 7,000 of MSM and 13,000 black African heterosexuals were unaware of their HIV infection) as well as of acquiring STIs and hepatitis.
