# Background

---

- Transmission of HIV in MSM in Europe remains at high levels.
- Greater rates of HIV testing and earlier ART initiation are proposed as means to reduce HIV incidence, by decreasing the number of MSM living with unsuppressed HIV viral load.
- In the UK, ~60% of HIV+ MSM (diagnosed and undiagnosed) are estimated to have viral suppression on ART

# Questions to be addressed

---

Taking the specific example of the HIV epidemic in MSM in the UK, and considering potential future increases in testing and changes in ART initiation threshold:

- What proportion of people with HIV should have viral suppression in order to reduce incidence below 1 per 1000 person years ? (i.e.  $\sim$  600 new infections per year)
- Will policies to increase testing be cost-effective ?

# HIV Synthesis Model

- Individual based stochastic simulation model
- Each time model program is run it simulates a dataset of the experience of the entire adult population of a country
- Variables in simulated data set:-

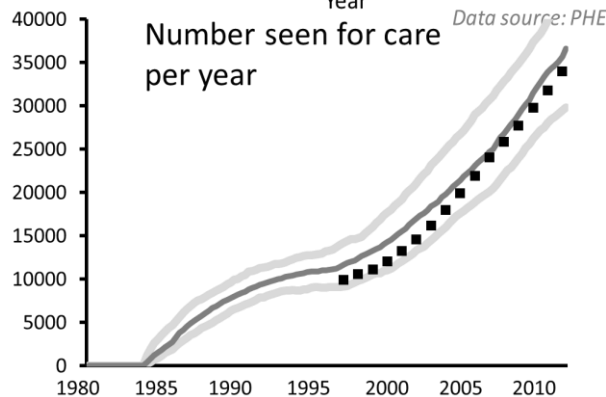

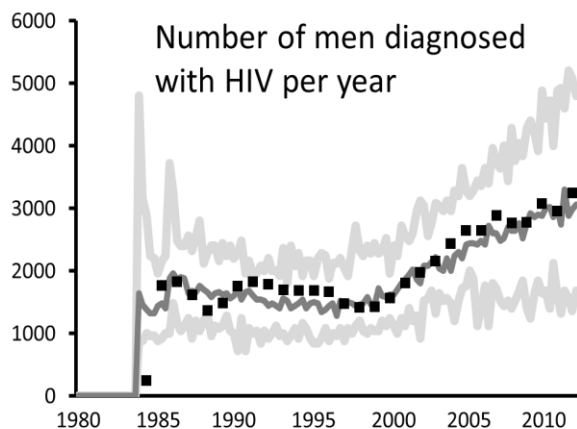

## Whole adult MSM population

Age  
Gender  
Condomless anal sex  
Current STI

## HIV positive MSM

Time from infection  
CD4 count  
Viral load  
Specific drugs  
Currently on ART  
Current adherence level  
Drug resistance mutations  
++

# Model-based analysis of the UK epidemic in MSM

# Potential increases in testing: Probability of diagnosis by time from infection

For those infected after 2015

Probability of having been diagnosed

# Potential increases in testing: Number of tests done per year

# Potential increases in testing and change in ART initiation criteria: Initiation of ART by time from infection

For those infected after 2015

Probability of having started ART

# Proportion of all HIV positive people with VL < 500

Proportion with VL < 500

# Cost effectiveness analysis

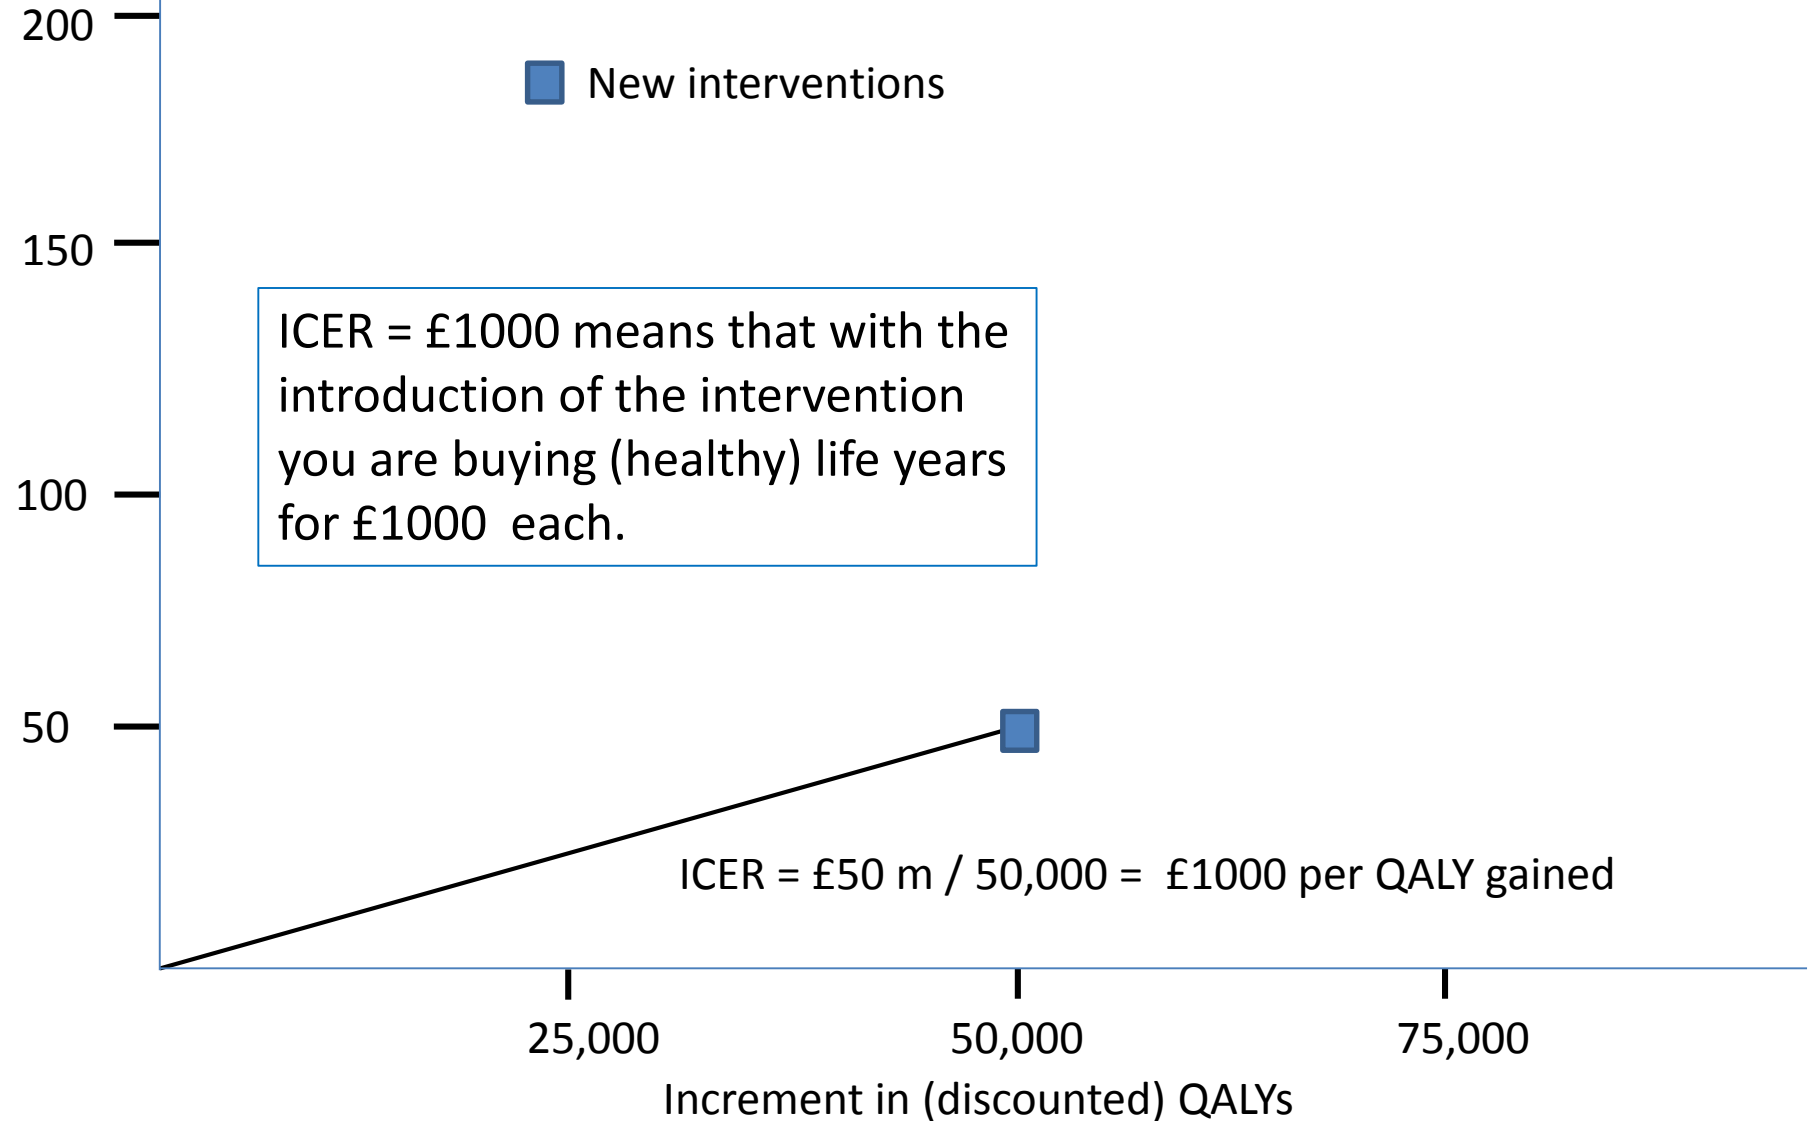

---

- A certain amount of resource spent on an effective intervention is buying (healthy) life years
- Cost effectiveness is about allocating resources such that any resources available for health care are used to buy the maximum number of (healthy) life years.
- Quality adjusted life year (QALY) = 1 year of healthy life

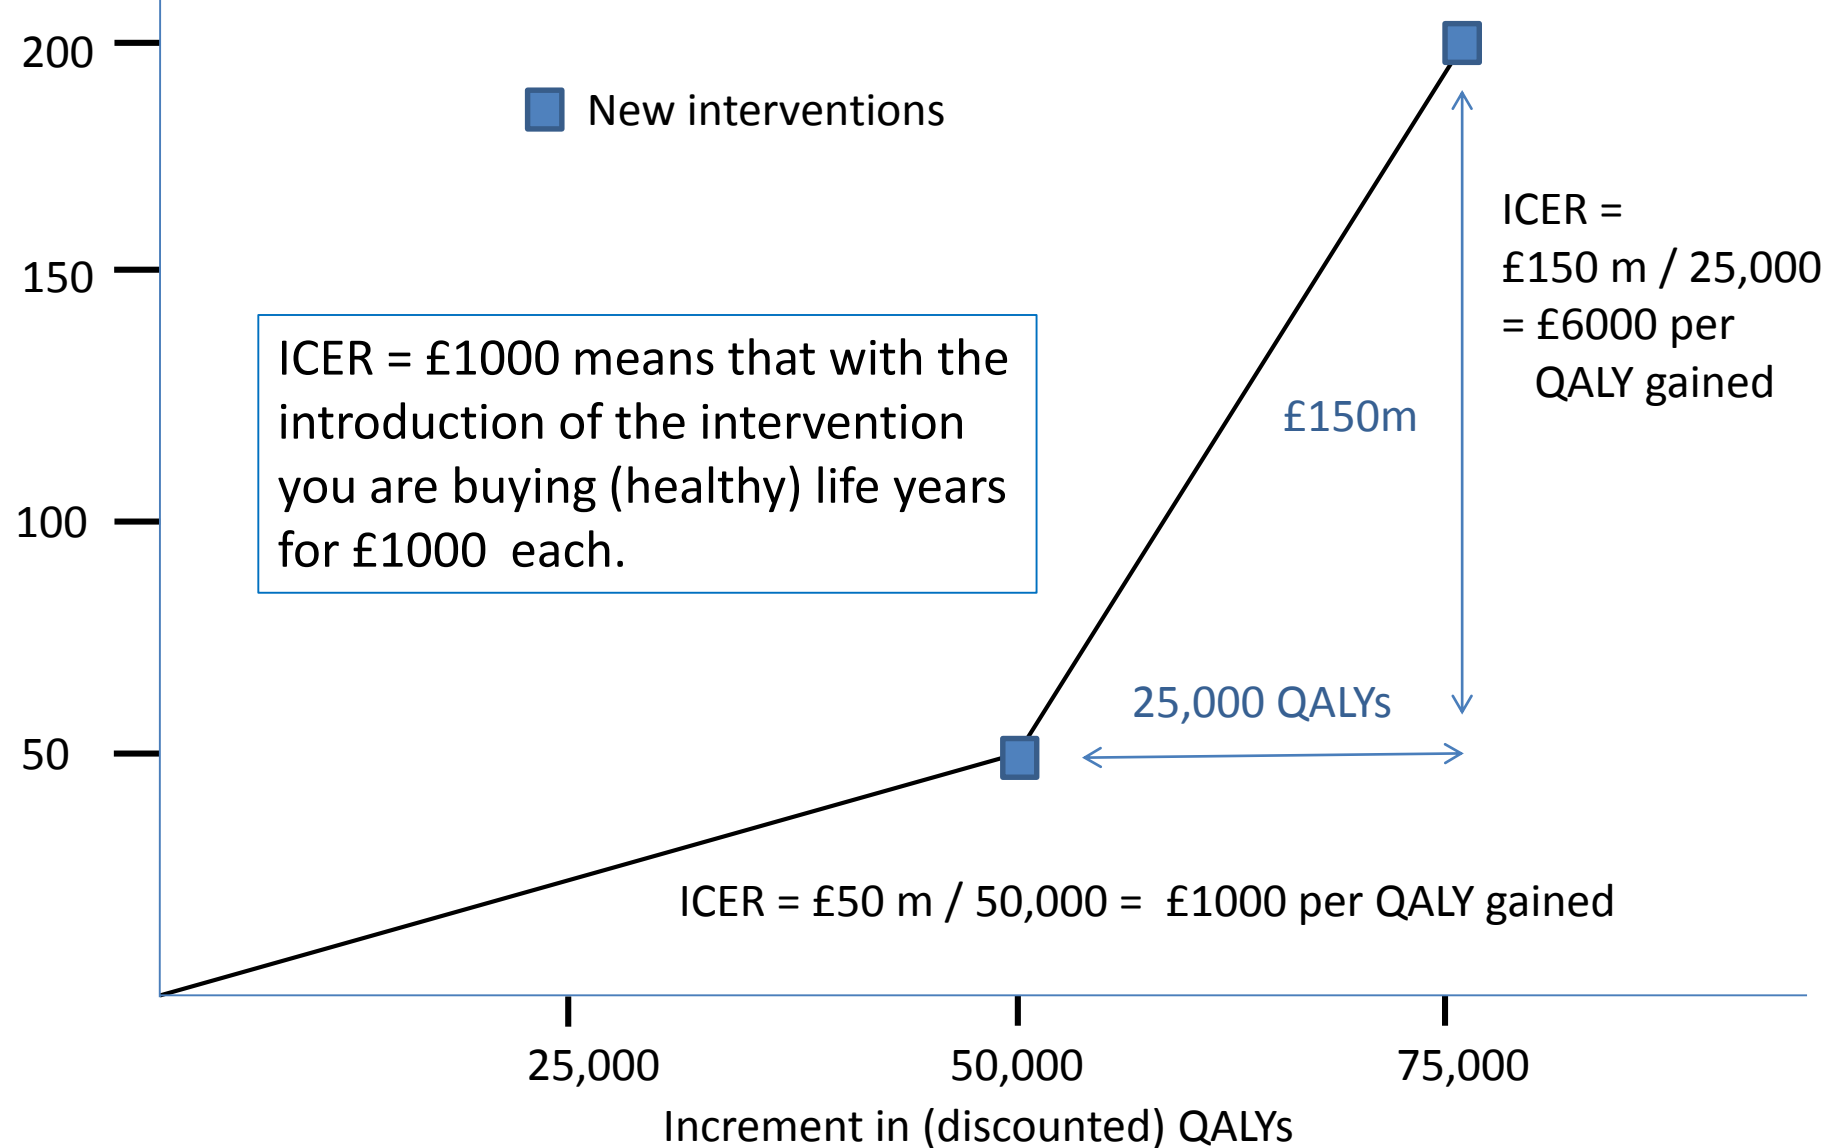

# Incremental cost effectiveness ratio (ICER) - concept

Increment in (discounted)  
cost (£million)

# Incremental cost effectiveness ratio (ICER) - concept

Increment in (discounted)  
cost (£million)

# Cost effectiveness analysis

---

- How low does the cost of the healthy life years produced (the ICER) need to be ?
- Consider ICER associated with every possible activity that results in health benefit.
- Implement them from cheapest up, until we have exhausted the health budget.
- Current UK working threshold £20,000 - £30,000
- For fixed or declining health budget, adopting any new intervention that incurs costs means displacing other interventions.

# Total cost of HIV care (discounted at 3.5% per year)

£ millions per year

# Difference in QALYs lived per year in entire MSM population compared with base test rate, ART at 350

Difference in number of discounted QALYs

# Incremental costs and QALYs over 15 years compared with base test rate, ART at 350

Increment in (discounted) cost (£million over 15 years)

# Incremental costs and QALYs over 15 years compared with base test rate, ART at 350

Increment in (discounted) cost (£million over 15 years)

test rate ++  
ART at 350  
ICER = £20,077

test rate ++  
ART at diagnosis  
ICER = £12,335

test rate +  
ART at 350

test rate +  
ART at  
diagnosis

base test rate ART  
at diagnosis

ICER remains < £20,000  
with £8m per year spent  
on campaigns / community  
mobilisation

Increment in (discounted) QALYs over 15 years

## Comments / Other issues

---

- Infections from men in primary infection
- Assume men with large numbers of condomless sex partners are not differentially resistant to testing or taking ART
- ART coverage in MSM visiting from abroad who have sex in the UK
- PrEP has been introduced in model (Cambiano et al presented at BASHH)

# Summary and conclusions

---

- What proportion of people with HIV should have viral suppression in order to reduce incidence below 1 per 1000 person years ?

*Around 90%. To achieve this requires:*

- *around 90% of people are diagnosed within 1 year of infection (currently < 50%),*
- *linkage, adherence and retention remain high*
- *ART is initiated at diagnosis (trial results awaited).*
- *levels of condomless sex do not increase significantly.*

# Summary and conclusions

---

- Will policies to increase testing in UK MSM be cost-effective ?

*Considering current drug prices, over a time horizon of 15 years or more, increased testing is likely to be cost effective.*

*If antiretroviral drug costs are substantially reduced with introduction of generics then increased testing is cost effective over a much shorter time horizon, and highly cost-effective if ART is initiated at diagnosis.*
